AI IN DEFENSE

From Technology to Operational Effect

A strategy deck based on the report: AI as operational infrastructure, not just technology adoption.

“AI is a tool. Operational effect is the mission.”

speed • security • sovereignty • human control

Core thesis

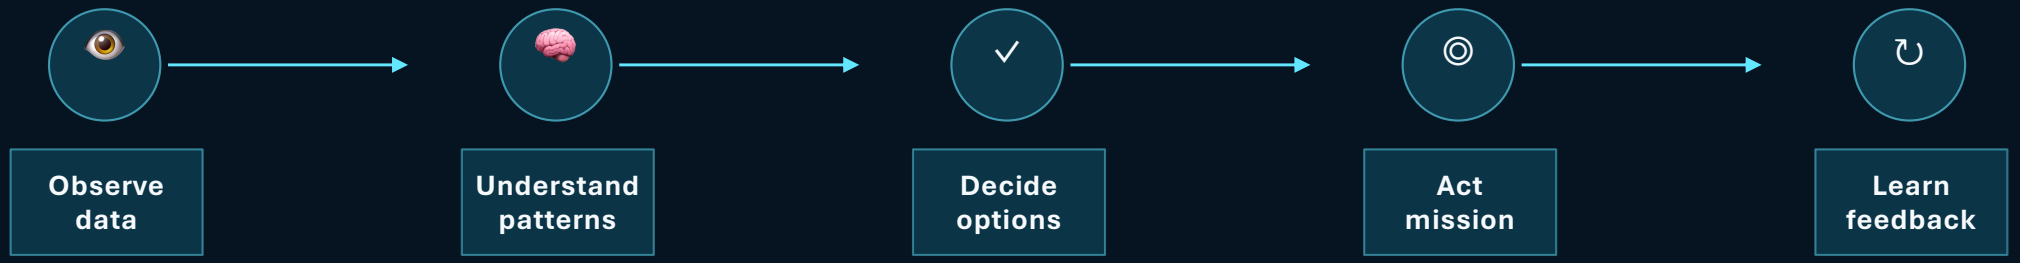
AI is moving from innovation-lab experiment to operational infrastructure

“The real task is not AI adoption. It is converting AI into operational effect.”

Operational effect
Better intelligence, faster decisions, stronger cyber defense, resilient logistics, safer rescue operations and improved readiness.

Learning system
Advantage comes from connecting data, compute, models, software, doctrine and feedback loops — not from one model alone.

Human control
AI must strengthen human judgment under pressure while preserving responsibility, accountability and command authority.



Why AI in defense matters now

The environment is becoming faster, more contested and more data-rich

Modern defense organizations face a convergence of drones, cyber operations, electronic warfare, satellite imagery, information operations, autonomous systems and compressed decision cycles.

The volume of information is growing faster than human staffs can process manually. AI becomes strategically important when it helps forces observe, understand, decide, act and learn faster — without losing control.

“The future battlefield will be shaped as much by data pipelines as by platforms.”

From technology adoption to operational capability

Defense AI must be judged by mission outcomes

A defense organization can experiment with impressive models and still fail to create operational capability. The practical test is whether AI improves performance in real missions, under real constraints, against real adversaries.

Situational awareness

clearer picture

Decision speed

shorter path to action

Readiness

availability and sustainment

Cognitive load

focus on what matters

Robustness

works under degradation

Mission value

faster, better command decisions

“AI is a tool. Operational effect is the mission.”

Main use cases

AI in defense is broader than drones or chatbots

Intelligence & sensor fusion
Fuse satellites, drones, sensors, cyber systems and open sources.

Drones, swarms & robotic systems
Extend reach, sensing, persistence and protection across air, sea and land.

Cyber defense & operations
Detect threats, prioritize incidents and respond closer to machine speed.

Logistics, maintenance & readiness
Predict needs, optimize supply chains and improve availability.

Training, simulation & wargaming
Create adaptive scenarios and intelligent opponents.

AI-enabled software development
Accelerate secure coding, testing and documentation.

Commander decision support
Structure information, quantify uncertainty and present options.

Edge AI in contested environments
Run locally when networks are jammed, degraded or denied.

Rescue, triage & medical robotics
Support casualty detection, evacuation and medical decision support.

Drones, swarms & robotic systems

A broader category than drones: autonomous systems across air, sea and land

Included systems
Autonomous aircraft, UAVs, collaborative combat aircraft, drone swarms, unmanned fast boats, UGVs, robot dogs, humanoid support robots, logistics robots and rescue robots.

Why swarms matter
A swarm changes the scale problem: distributed sensing, wider coverage, graceful degradation and resilience — with increased control and escalation challenges.

Design principle
Mission boundaries, stop conditions, audit trails, identification rules and human supervision must be built in from the beginning.

Use serious operational language: “robotic systems”, “autonomous platforms”, “force protection” and “human-machine teaming”.

Rescue, triage & medical robotics

Human-supervised systems that protect medics and improve evacuation speed

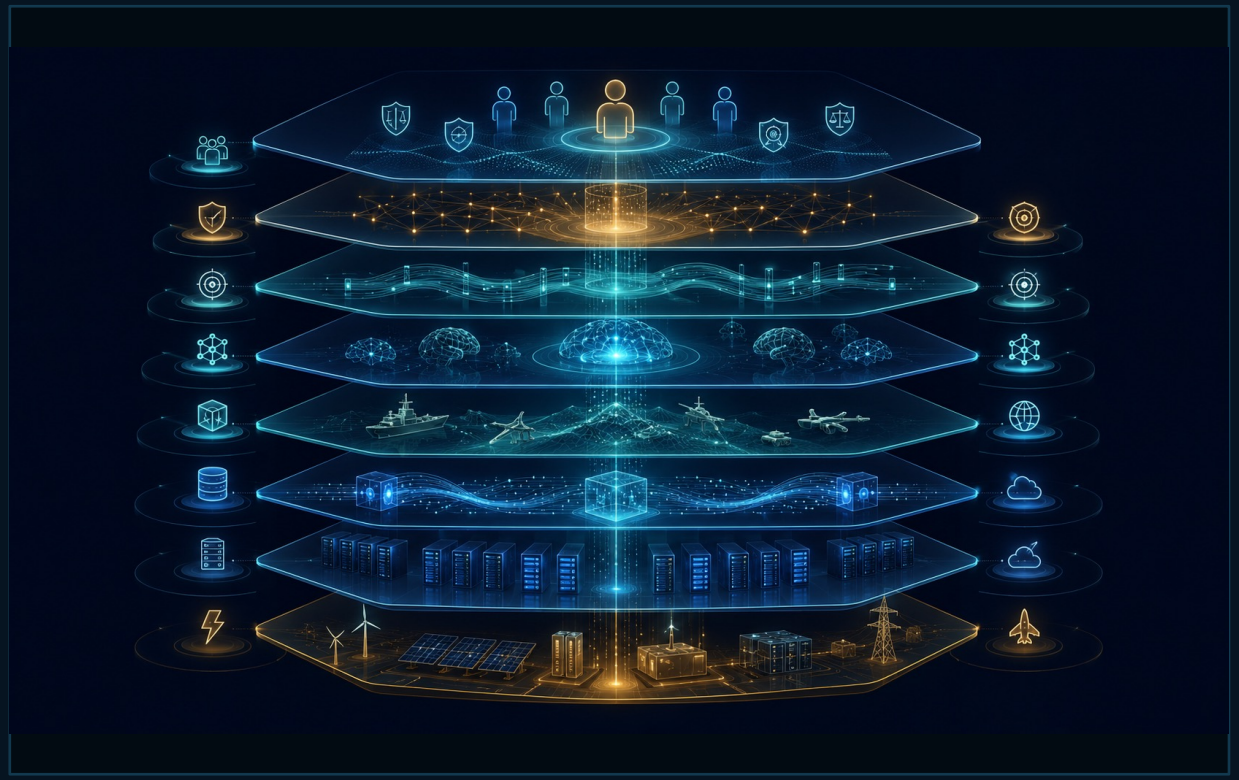
The credible near-term story is not “autonomous humanoid battlefield surgeons.” It is AI-supported casualty detection, triage, evacuation and medical decision support — helping medics and surgeons work faster, safer and with better information.

What it enables
Casualty location, urgency assessment, medical supply delivery, robotic stretchers, autonomous evacuation support and remote medical guidance.

Human control remains central
Medical judgment, trust, safety and accountability must remain human-supervised and clinically governed.

The AI defense stack

The capability is the stack — not the model alone



People & doctrine
human expertise, command, training and rules

Governance & control
law, ethics, security, audit and accountability

Command integration
decision processes, workflows and systems

Simulation & test
validation, red-teaming and adversarial evaluation

Models & agents
foundation models, specialist models and agents

Data & environments
quality, classification, sharing and storage

Compute & infrastructure
chips, cloud, edge and secure data centers

Energy foundation
reliable power and resilient infrastructure

“AI advantage is not one model. It is a learning system.”

Defense AI is different from consumer AI

The operating environment is hostile, degraded and adversarial

“Defense AI must work when data is incomplete, networks are degraded and the adversary is trying to deceive it.”

Higher standard
Robust under pressure, secure by design, auditable, and tested in realistic conditions.

Failure-mode thinking
What happens when AI is wrong, uncertain, attacked, over-trusted or behaves unexpectedly?

Human responsibility
AI can support judgment, but command includes intent, law, ethics and accountability.

A system that performs well in a demo may fail under real operational pressure. Defense AI must be evaluated for performance, robustness, security, failure modes and operational usefulness.

Risks and constraints

AI creates new capabilities — and new failure modes

Misinformation & hallucination
plausible but wrong answers

Adversarial manipulation
spoofed sensors, falsified data

Cybersecurity
models, prompts and data as targets

Escalation risk
compressed timelines and autonomy

Supplier dependency
foreign cloud, chips and models

Over-automation
weakened human judgment

“Speed without control is dangerous. Control without speed is too slow.”

The answer is speed with control: short cycles, realistic testing, built-in governance, clear accountability and continuous operator feedback.

The institutional challenge

AI adoption is organizational transformation, not only technical implementation

Defense organizations were built for reliability, hierarchy, accountability and risk control. AI also demands experimentation, iteration, software updates, data sharing and rapid operator feedback. The challenge is to combine speed with control.

Mandate

AI leadership with authority

Teams

cross-functional sprint teams

Operators

close contact with the field

Security

law and governance from day one

Partners

NATO, allies, academia, startups and industry

Learning

evaluation and continuous improvement

“AI adoption in defense is institutional learning.”

Europe, NATO and Denmark

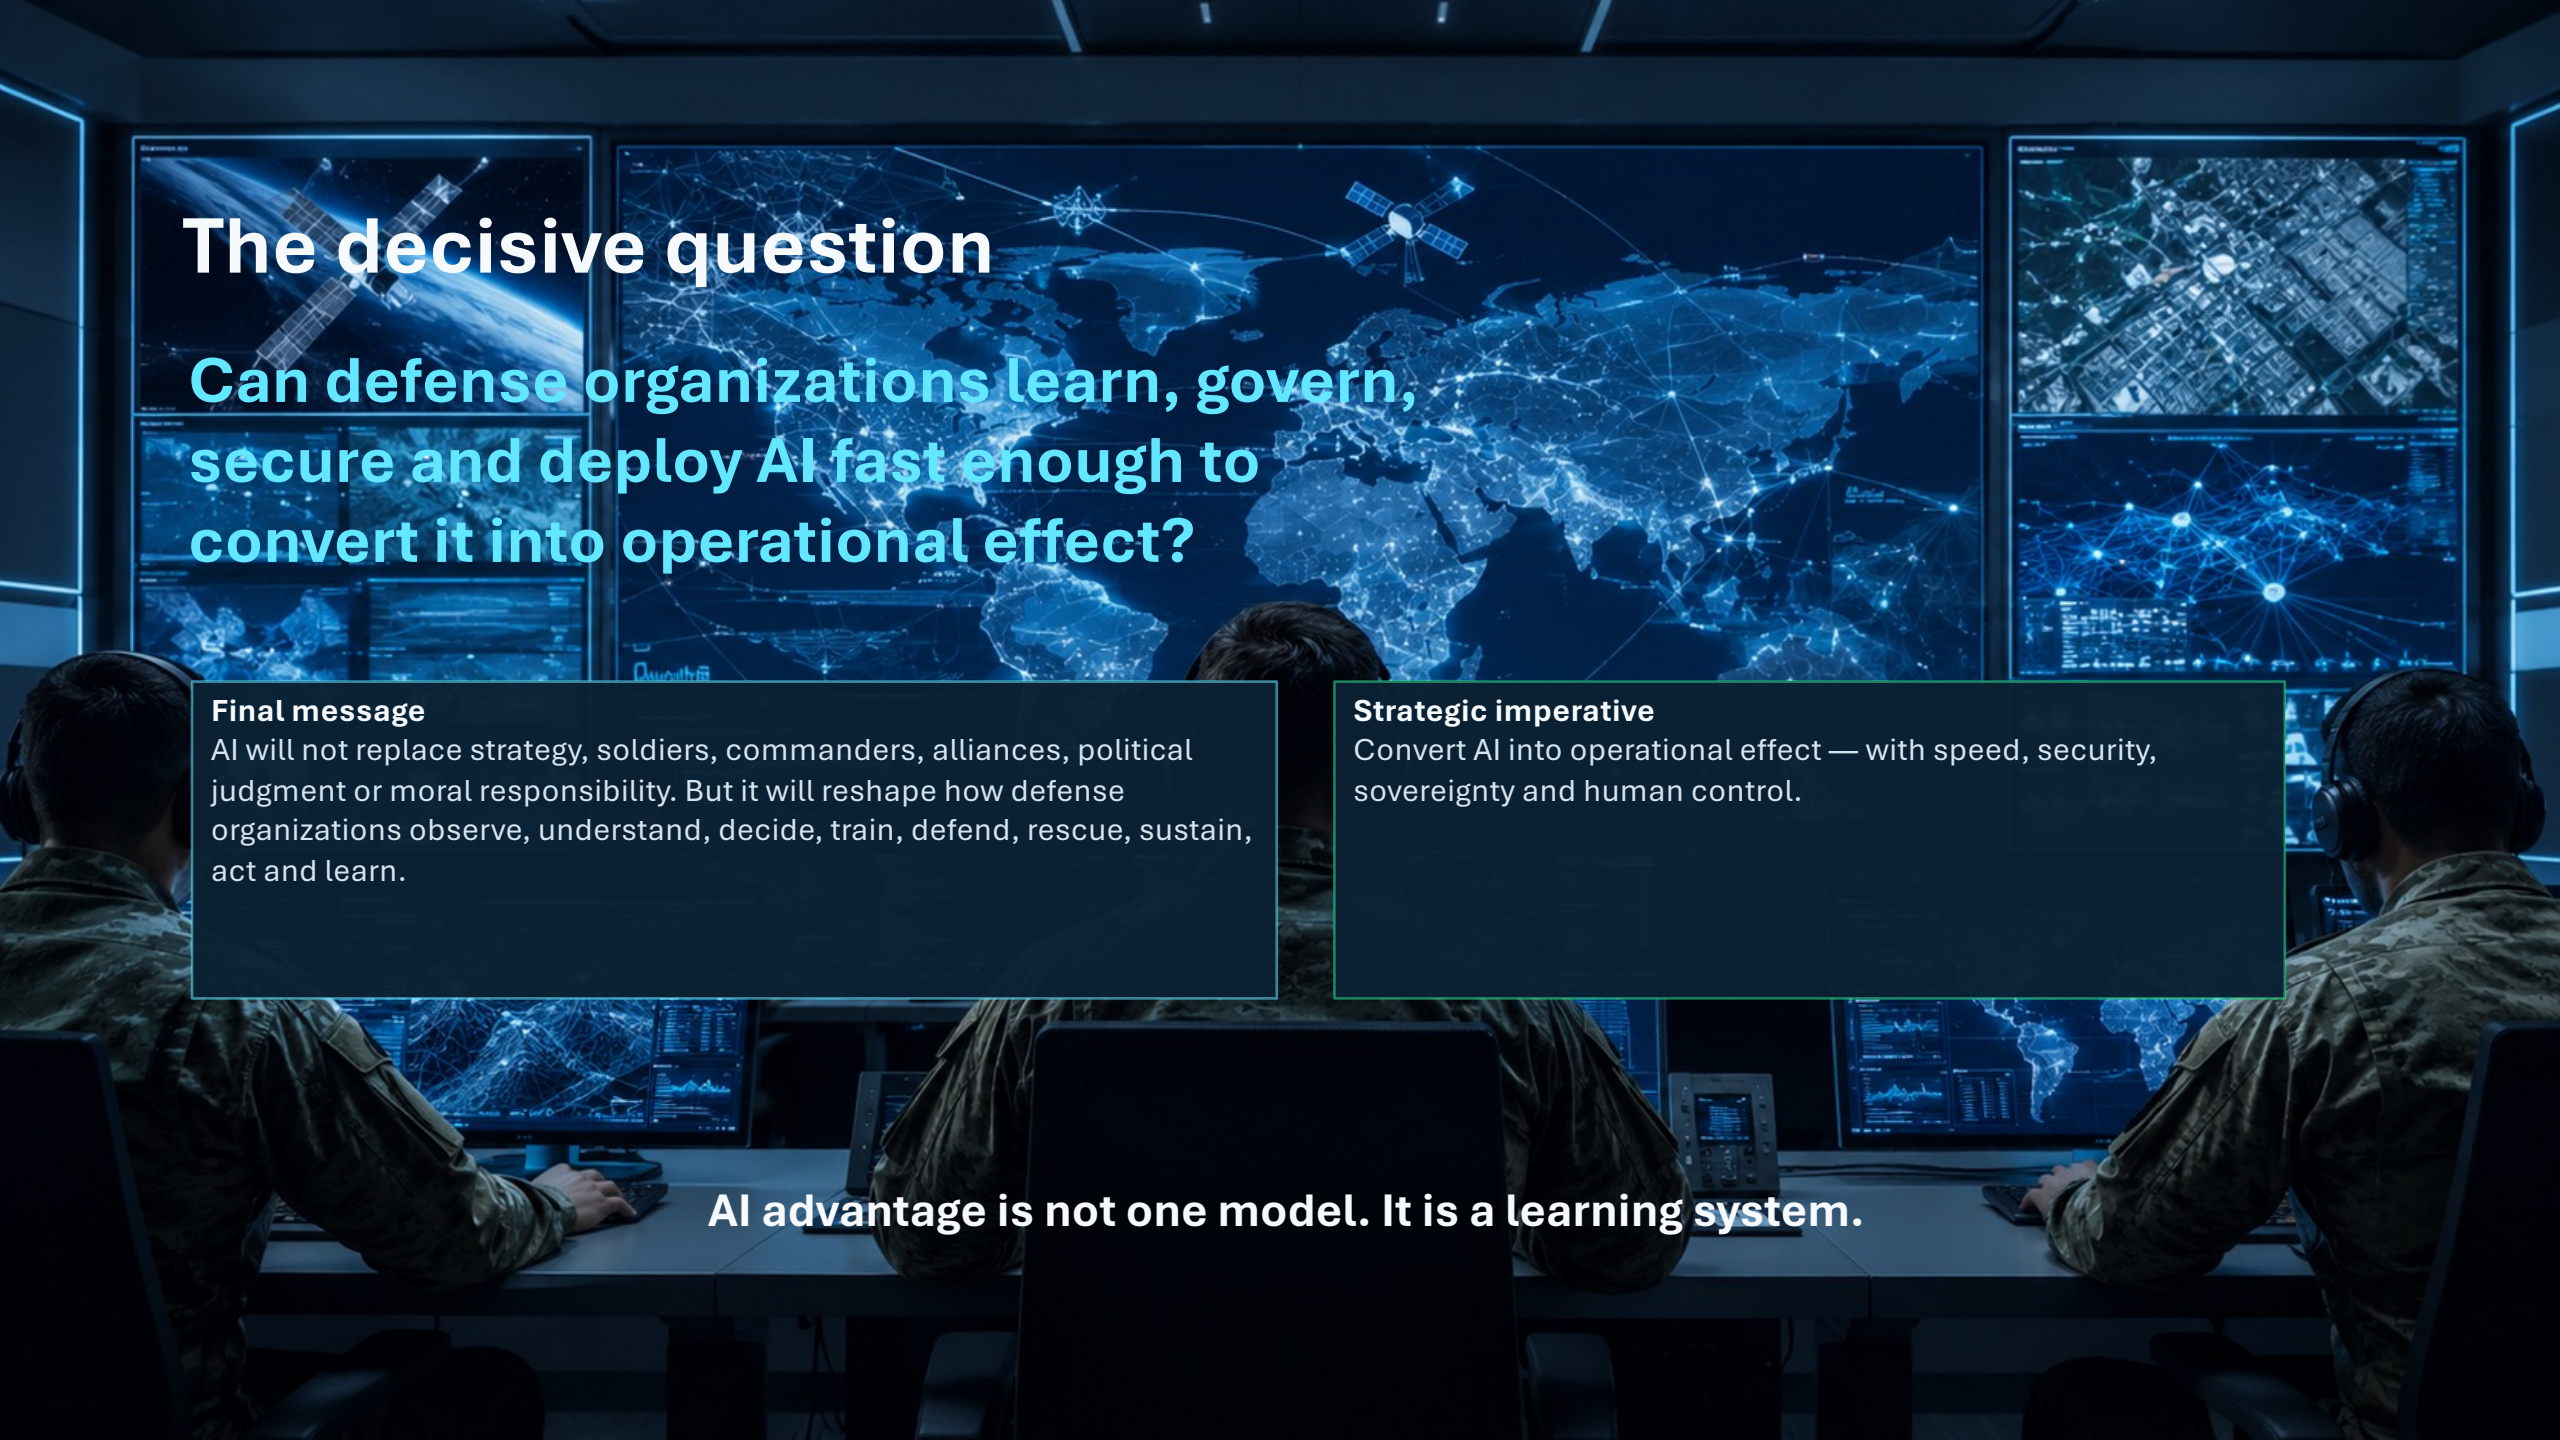
Sovereignty means resilience, not isolation

Allied by design
NATO interoperability and cooperation with allies remain essential. Defense AI must fit into shared operational and security frameworks.

Trusted ecosystems
Governments, armed forces, universities, startups, established industry and secure compute infrastructure must be connected.

Focused strengths
Smaller countries can build high-trust capabilities in maritime awareness, cyber defense, logistics, drones, simulation, command support and rescue robotics.

**“Open innovation where possible.
Classified deployment where necessary.”**



The decisive question

Can defense organizations learn, govern, secure and deploy AI fast enough to convert it into operational effect?

Final message
AI will not replace strategy, soldiers, commanders, alliances, political judgment or moral responsibility. But it will reshape how defense organizations observe, understand, decide, train, defend, rescue, sustain, act and learn.

Strategic imperative
Convert AI into operational effect — with speed, security, sovereignty and human control.

AI advantage is not one model. It is a learning system.
